

# Landing on Europa: Challenges, Technologies, and Strategy

Miguel San Martin

Jet Propulsion Laboratory, California Institute of Technology

AAS Rocky Mountain GN&C Conference  
Breckenridge, Colorado  
February 5, 2017

# Why Explore Europa?

Pre-Decisional Information -- For Planning and Discussion Purposes Only

# Why Explore Europa?

---

Pre-Decisional Information -- For Planning and Discussion Purposes Only

# Mission Concept Goals

---

Assess the habitability of Europa via in-situ techniques uniquely available to a lander mission

Search for evidence of life on Europa

Characterize surface and subsurface properties at the scale of the lander to support future exploration

# De-Orbit, Descent, and Landing (DDL) Challenges

Current Lack of High-res Recon  
Maps

Highest Resolution Europa  
image currently available

JPL

Europa "Freckles"  
(spots each ~10km across)

Highly Hazardous &  
Unknown Terrain

Ultra-high Radiation

Limited Lander  
SWAP Resources

Large Propulsive  
Delta-V

# Terrain Uncertainty

---

- Little is known about the surface topography of Europa
  - 36% of surface imaged at 1 km/pxl
  - A few highly localized areas at 50 m/pxl
- Europa Lander concept would launch before we obtain any new information about Europa surface topography

**Europa Lander concept must be robust  
to a wide variety of terrain types**

# Examples of Europa Terrain

Pre-Decisional Information -- For Planning and Discussion Purposes Only

# Penitentes

---

Pre-Decisional Information -- For Planning and Discussion Purposes Only

# Delivery Error

---

- Europa Lander would approach Europa at Start of DDL with a surface relative velocity of  $\sim 1950$  m/s
- The Lander would be delivered to the start of the de-orbit burn with an along-track position error of about  $\pm 4500$  m ( $3\sigma$ )
- The solid rocket motor errors would contribute as much as  $\pm 4$  km ( $3\sigma$ ) in along-track position error at de-orbit burn termination
- Collective opinion of the Europa scientific and engineering community is that it is unlikely that we will find a 9 km-long region on Europa that is scientifically interesting, accessible, and safe to land

# Radiation

---

- Jupiter's magnetosphere traps and accelerates particles in a torus-like structure of radiation belts
  - Europa orbits Jupiter well within the high-radiation zone so radiation exposure to the Lander can only be minimized, not avoided
- Lander would be expected to experience a total ionizing dose (TID) of  $\sim 1.7$  Mrad, primarily from electrons, behind 100 mil of aluminum
  - To attenuate the expected dose to 150 krad (Si), most electronics would be housed in a radiation vault
- Majority of the dose (both TID and displacement damage) would be accumulated in the end-phase of the mission
  - Long non-operational cruise duration coupled with the short and abrupt DDL phase implies that the time at which the best performance is required from the sensors and electronics coincides with the end-of-life or end-of-lander mission segment

# Planetary Protection

---

- Europa Lander must comply with Category IV NASA planetary protection requirements:
  - The probability of delivering to the surface of Europa a single viable terrestrial microorganism must be less than  $10^{-4}$
- This has great implications on the development, procurement, and processing of GN&C hardware element
- The project is evaluating a series of sterilization alternatives
  - Cleaning
  - Dry-heat microbial reduction (DHMR)
  - On-board incineration devices

# Precision Landing with TRN and HDA

**Separation**  
T -30 hours max

**De-Orbit Burn**  
1950 m/s, @ T -5 min

**Burnout & Separation**

**Intelligent Landing System (ILS)**  
LVS/TRN Localization & Site Targeting  
Error Ellipse ~ 4.0 km X 1.2 km ( $3\sigma$  Preliminary)

**On Nominal Landing Site**

**Hazard Detection & Avoidance (ILS)**

**Sky Crane Maneuver**

**Pin Point Landing & Fly-Away**

**Self Righting**

Altitude  
5 km

1 km

500 m

30 m

0 m

**Error Ellipse < 50-100 m**

- For Planning and Discussion Purposes Only

# SkyCrane with Landing Stabilizers

Lander

SkyCrane Delivery

Lander Detail (Deployed Configuration)

# Flight System Concept

# DDL Strategy

# Intelligent Landing System (ILS) Concept of Operations

visible descent imaging

**Terrain Relative Navigation (TRN)**  
image landmark matching

**Velocimetry**  
image feature tracking

lidar terrain  
mapping

**Hazard Detection (HD)**  
wide beam lidar

**Altimetry**  
narrow beam  
lidar

**Dual Function Lidar**

# Summary

---

- Europa is a very important science target for the study of astrobiology, and a mission to its surface would provide the greatest insight on this subject
- Landing on Europa presents a series of difficult challenges, the main being uncertain terrain and the radiation environment
- A DDL and GN&C architecture has been developed that addresses these challenges by implementing the following technologies
  - Precision Landing enabled by Terrain Relative Navigation
  - Hazard Detection and Avoidance based on 3D-LIDAR
  - SkyCrane and Landing Stabilizers for touchdown
